- ▶ This chapter is intended for making preparations for subsequent chapters.
- ▶ The content contained is about the static structure of program and how CPU executes a program.

# Assembly Basics

## Register

Software Security

Suppose we write a C file code, containing the following procedure definition:

```
1 int accum = 0;
2
3 int sum(int x, int y)
4 {
5     int t = x + y;
6     accum += t;
7     return t;
8 }
```

The assembly file contains various declaration including the set of lines:

Offset	Bytes	Equivalent assembly language
0:	55	push %ebp
1:	89 e5	mov %esp,%ebp
3:	8b 45 0c	mov 0xc(%ebp),%eax
5:	03 45 08	add 0x8(%ebp),%eax
6:	01 05 00 00 00 00	add %eax,0x0
7:	5d	pop %ebp
8:	c3	ret

# Assembly Basics

## Register

Suppose we write a C file code, containing the following procedure definition:

```
1 int accum = 0;
2
3 int sum(int x, int y)
4 {
5     int t = x + y;
6     accum += t;
7     return t;
8 }
```

The assembly file contains various declaration including the set of lines:

Offset	Bytes	Equivalent assembly language
0:	55	push %ebp
1:	89 e5	mov %esp,%ebp
3:	8b 45 0c	mov 0xc(%ebp),%eax
5:	03 45 08	add 0x8(%ebp),%eax
6:	01 05 00 00 00 00	add %eax,0x0
7:	5d	pop %ebp
8:	c3	ret

## Questions

- ▶ 1.push? mov? add? pop? ret?
- ▶ 2.%esp? %ebp? %eax?

## Simple Memory Addressing Modes

7

### ► 1.Normal (R) Mem[Reg[R]]

- ▶ Register R specifies memory address
- ▶ Aha! Pointer dereferencing in C
- ▶ Example: `movq (%ecx),%eax`

### ► 2.Displacement D(R) Mem[Reg[R]+D]

- ▶ Register R specifies start of memory region
- ▶ Constant displacement D specifies offset
- ▶ Example: `movq 8(%ebp),%edx`

# Assembly Basics

## Memory Addressing Modes

Software Security

## Complete Memory Addressing Modes

8

### ► 1. Most General Form D(Rb,Ri,S)

$\text{Mem}[\text{Reg}[\text{Rb}]+\text{S}^*\text{Reg}[\text{Ri}]+\text{D}]$

- D: Constant "displacement" 1, 2, or 4 bytes
- Rb: Base register: Any of 16 integer registers
- Ri: Index register: Any, except for
- S: Scale: 1, 2, 4, or 8 (why these numbers?)

### ► 2. Special Cases

- (Rb,Ri):  $\text{Mem}[\text{Reg}[\text{Rb}]+\text{Reg}[\text{Ri}]]$
- (Rb,Ri):  $\text{Mem}[\text{Reg}[\text{Rb}]+\text{Reg}[\text{Ri}]+\text{D}]$
- (Rb,Ri,S):  $\text{Mem}[\text{Reg}[\text{Rb}]+\text{S}^*\text{Reg}[\text{Ri}]]$

### ► 1. Most General Form D(Rb,Ri,S)

$\text{Mem}[\text{Reg}[Rb] + S * \text{Reg}[Ri] + D]$

- D: Constant "displacement" 1, 2, or 4 bytes
- Rb: Base register: Any of 16 integer registers
- Ri: Index register: Any, except for
- S: Scale: 1, 2, 4, or 8 (why these numbers?)

### ► 2. Special Cases

- (Rb,Ri):  $\text{Mem}[\text{Reg}[Rb] + \text{Reg}[Ri]]$
- (Rb,Ri):  $\text{Mem}[\text{Reg}[Rb] + \text{Reg}[Ri] + D]$
- (Rb,Ri,S):  $\text{Mem}[\text{Reg}[Rb] + S * \text{Reg}[Ri]]$

## Memory Addressing Modes

Software Security

## Practice Problem

Assume the following values are stored at the indicated memory addresses and registers:

Address	Value	Register	Value
0x100	0xFF	%eax	0x100
0x104	0xAB	%ecx	0x1
0x108	0x13	%edx	0x3
0x10C	0x11		

Fill in the following table showing the values for the indicated operands:

Operand	Value
%eax	_____
0x104	_____
\$0x108	_____
(%eax)	_____
4(%eax)	_____
9(%eax,%edx)	_____
260(%ecx,%edx)	_____
0xFC(%ecx,4)	_____
(%eax,%edx,4)	_____

## Moving data

### Moving data

- ▶ mov Source, Dest:

### Operand Types

- ▶ 1.Immediate: Constant integer data
  - ▶ Example: 0x400,-533
  - ▶ Example: 0x400,-533
  - ▶ Encoded with 1, 2, or 4 bytes
- ▶ 2.Register: One of 16 integer registers
  - ▶ Example: %eax, %r13
  - ▶ But %esp reserved for special use
  - ▶ Others have special uses for particular instructions
- ▶ 3.Memory:address given by register
  - ▶ Simplest example:(%eax)
  - ▶ Various other "address modes"

## MOV Operand Combinations

### ► Data Movement Instruction

- The instructions in the mov class copy their source values to their destinations. The source operand comes first and the destination second:

1	<code>movl \$0x4050,%eax</code>	<i>Immediate--Register, 4 bytes</i>
2	<code>movw %bp,%sp</code>	<i>Register--Register, 2 bytes</i>
3	<code>movb (%edi,%ecx),%ah</code>	<i>Memory--Register, 1 byte</i>
4	<code>movb \$-17,(%esp)</code>	<i>Immediate--Memory, 1 byte</i>
5	<code>movl %eax,-12(%ebp)</code>	<i>Register--Memory, 4 bytes</i>

Software Security

## Practice Problem

### Practice Problem

For each of the following lines of assembly language, determine the appropriate instruction suffix based on the operands. (For example, `mov` can be rewritten as `movb`, `movw`, or `movl`.)

```
1    mov    %eax, (%esp)
2    mov    (%eax), %dx
3    mov    $0xFF, %bl
4    mov    (%esp,%edx,4), %dh
5    push   $0xFF
6    mov    %dx, (%eax)
7    pop    %edi
```

### Practice Problem

Each of the following lines of code generates an error message when we invoke the assembler. Explain what is wrong with each line.

```
1    movb $0xF, (%bl)
2    movl %ax, (%esp)
3    movw (%eax),4(%esp)
4    movb %ah,%sh
5    movl %eax,$0x123
6    movl %eax,%dx
7    movb %si, 8(%ebp)
```

0x108	0x13	%edx	0x3
0x10C	0x11		

Fill in the following table showing the effects of the following instructions, both in terms of the register or memory location that will be updated and the resulting value:

Instruction	Destination	Value
addl %ecx, (%eax)		
subl %edx, 4(%eax)		
imull \$16, (%eax,%edx,4)		
incl 8(%eax)		
decl %ecx		
subl %edx,%eax

# Assembly Basics

## Moving data

27

The final group consists of shift operations, where the shift amount is given first, and the value to shift is given second.

SAL	$k, D$	$D \leftarrow D \ll k$	Left shift
SHL	$k, D$	$D \leftarrow D \ll k$	Left shift (same as SAL)
SAR	$k, D$	$D \leftarrow D \gg_A k$	Arithmetic right shift
SHR	$k, D$	$D \leftarrow D \gg_L k$	Logical right shift

# Assembly Basics

## Moving data

Software Security

## Practice Problem

Suppose we want to generate assembly code for the following C function:

```
int shift_left2_rightn(int x, int n)
{
    x <= 2;
    x >= n;
    return x;
}
```

The code that follows is a portion of the assembly code that performs the actual shifts and leaves the final value in register `%eax`. Two key instructions have been omitted. Parameters `x` and `n` are stored at memory locations with offsets 8 and 12, respectively, relative to the address in register `%ebp`.

```
1      movl  8(%ebp), %eax    Get x
2      _____           x <= 2
3      movl  12(%ebp), %ecx    Get n
4      _____           x >= n
```

Fill in the missing instructions, following the annotations on the right. The right shift should be performed arithmetically.

# Assembly Basics

## Control Codes

Software Security

## Practice Problem

The following C code

```
int comp(data_t a, data_t b) {  
    return a COMP b;  
}
```

shows a general comparison between arguments **a** and **b**, where we can set the data type of the arguments by declaring **data\_t** with a **typedef** declaration, and we can set the comparison by defining **COMP** with a **#define** declaration.

Suppose **a** is in **%edx** and **b** is in **%eax**. For each of the following instruction sequences, determine which data types **data\_t** and which comparisons **COMP** could

cause the compiler to generate this code. (There can be multiple correct answers; you should list them all.)

- A. `cmpl %eax, %edx  
setl %al`
- B. `cmpw %ax, %dx  
setge %al`
- C. `cmpb %al, %dl  
setb %al`
- D. `cmpl %eax, %edx  
setne %al`

## Control Codes

Software Security

## Practice Problem

The following C code

```
int test(data_t a) {  
    return a TEST 0;  
}
```

shows a general comparison between argument `a` and 0, where we can set the data type of the argument by declaring `data_t` with a `typedef`, and the nature of the comparison by declaring `TEST` with a `#define` declaration. For each of the following instruction sequences, determine which data types `data_t` and which comparisons `TEST` could cause the compiler to generate this code. (There can be multiple correct answers; list all correct ones.)

- A. `testl %eax, %eax`  
`setne %al`
- B. `testw %ax, %ax`  
`sete %al`
- C. `testb %al, %al`  
`setg %al`
- D. `testw %ax, %ax`  
`seta %al`

## Control Codes

## Practice Problem

In the following excerpts from a disassembled binary, some of the information has been replaced by **Xs**. Answer the following questions about these instructions.

- A. What is the target of the **je** instruction below? (You don't need to know anything about the **call** instruction here.)

804828f:	74 05	je	XXXXXX
8048291:	e8 1e 00 00 00	call	80482b4

- B. What is the target of the **jb** instruction below?

8048357:	72 e7	jb	XXXXXX
8048359:	c6 05 10 a0 04 08 01	movb	\$0x1,0x804a010

- C. What is the address of the **mov** instruction?

XXXXXX:	74 12	je	8048391
XXXXXX:	b8 00 00 00 00	mov	\$0x0,%eax

- D. In the code that follows, the jump target is encoded in PC-relative form as a 4-byte, two's-complement number. The bytes are listed from least significant to most, reflecting the little-endian byte ordering of IA32. What is the address of the jump target?

80482bf:	e9 e0 ff ff ff	jmp	XXXXXX
80482c4:	90	nop	

- E. Explain the relation between the annotation on the right and the byte coding on the left.

80482aa:	ff 25 fc 9f 04 08	jmp	*0x8049ffc
----------	-------------------	-----	------------

# Object Files

## ELF

Software Security

Object files are merely collections of blocks of bytes.  
Some of these blocks contain program code, others contain  
program data, and others contain data structures that guide the  
linker and loader.

# Object Files

## ELF

### Object files come in three forms:

- ▶ Relocatable object file
  - ▶ Contains binary code and data in a form that can be combined with other relocatable objects files at compile time to create an executable object file.
- ▶ Executable object file
  - ▶ Contains binary code and data in a form that can be copied directly into memory and executed
- ▶ Shared object file
  - ▶ A special type of relocatable object file that can be loaded into memory and linked dynamically, at either load time or run time

# Objects Files

## ELF

Object file formats vary from system to system.

- ▶ Early versions of System V Unix used the Common Object File format(COFF)
- ▶ Windows NT uses a variant of COFF called the Portable Executable(PE) format
- ▶ Modern Unix system—such as Linux, later version of System V Unix, BSD Unix variants, and Sun Solaris—use the Unix Executable and Linkable Format(ELF)

Describes object file sections	Section header table

Typical ELF relocatable object file

The section header table describes the locations and sizes of the various sections, and contains a fixed sized entry for each section in the object file.

# Objects Files

## Symbols and Symbol Tables

Software Security

A symbol table with information about functions and global variables that are defined and referenced in the program. Each relocatable object module, m, has a symbol table that contains information about the symbols that are defined and referenced by m.

# Objects Files

## Symbols and Symbol Tables

- ▶ Global symbols that are defined by module m and that can be referenced by other modules. Global linker symbols correspond to nonstatic C functions and global variables that are defined without the C static attribute.
- ▶ Global symbols that are referenced by module m but defined by some other module. Such symbols are called externals and correspond to C functions and variables that are defined in other modules.
- ▶ Local symbols that are defined and referenced exclusively by module m. Some local linker symbols correspond to C functions and global variables that are defined with the static attribute. These symbols are visible anywhere within module m, but cannot be referenced by other modules. The sections in an object file and the name of the source file that correspond to module m also get local symbols.

## Procedures

- ▶ A procedure call involves passing both data(in the form of procedure parameters and return values) and control from one part of a program to another. In addition, it must allocate space for the local variables of the procedures on entry and deallocate them on exit. Most machines, including IA32, provide only simple instructions for transferring control to and from procedures. The passing of data and the allocation and deallocation of local variables is handled by manipulating the program stack.

### Practice Problem:

A C function `fun` has the following code body:

```
*p = d;  
return x-c;
```

The IA32 code implementing this body is as follows:

```
1    movsb 12(%ebp),%edx  
2    movl 16(%ebp), %eax  
3    movl %edx, (%eax)

### CALL , RET和LEAVE

CALL指令的步骤：首先是将返回地址（也就是call指令要执行时EIP的值）压入栈顶，然后是将程序跳转到当前调用的方法的起始地址。执行push和jump指令。

RET指令则是将栈顶的返回地址弹出到EIP，然后按照EIP此时指示的指令地址继续执行程序。

LEAVE指令是将栈指针指向帧指针，然后POP备份的原帧指针到%EBP。

# Procedures

## Linux Stack Frame

```
push %ebp:  
    sub $4, %esp  
    mov %ebp, (%esp)  
  
pop %ebp:  
    mov (%esp), %ebp  
    add $4, %esp  
  
leave:  
    mov %ebp, %esp  
    pop %ebp  
  
call:  
    Push the ret on the stack  
    Jump to the target address(the start address of function called)  
  
ret:  
    pop the ret(stored on stack) to %eip  
    back to the address
```
